Research statement

Physics program

Despite its success, the Standard Model of Particle Physics is known to be only an effective theory. The most well known extension to the Standard Model is Supersymmetry (SUSY). It could solve several short comings of the Standard Model, most notably the hierarchy problem and the missing dark matter candidate. The understanding of the nature of dark matter is one of the biggest goals of physics right now. Even when it would not be explained within SUSY, searches for SUSY particles cover a wide range of the phase-space, due to its nature with many unknown parameters. Now that we discovered the Higgs Boson, SUSY searches will become the driving force for finding thitherto unknown particles. It is of outmost importance to carry on these efforts, even when first searches didn't show any hint of SUSY particles. The unknown SUSY breaking mechanism could drive the particles to higher masses without interfering with naturalness arguments.

Strongly charged SUSY particles have the highest production cross-section for a given mass at the LHC. However, no signs of these particles have been found so far and it might be that electroweak SUSY particles have a considerable lower mass and become the dominant SUSY process at the LHC. During my term as a PhD student at the University of Bern I mainly worked on an electroweak SUSY search in a final state with three leptons. I developed a method to optimize and bin a signal region. By applying my method, I successfully pushed existing exclusion limits on SUSY particle masses by about 100 GeV in a specific model, without the use of additional data. I was the leading analyst in this search and also carried out the statistical interpretation of the search results. The paper was published in JHEP and also presented in the CERN courier journal. In total I worked on three papers and four ATLAS-CONF notes, all with a final state of either three or four leptons. For two publications, I represented the analysis group on a SUSY approval. I'm still working in close collaboration with the SUSY electroweak group, where I'm sometimes consulted as an expert.

When the LHC underwent a technical overhaul, the center of mass energy raised from 8 TeV to 13 TeV. The cross-section ratio gain is by far the largest for strongly produced SUSY particles. In a PUB note, it was shown that for a final state with one lepton, even a few inverse femtobarn are enough, to have the same sensitivity as the full 8 TeV dataset.

Detector

As a PhD student I worked on the readout electronics of the insertable b-layer (IBL). I tested optical receivers to be used for the readout for reliability, frequency and input sensitivity. I defined the tests and performed them, using amongst others FPGA's. To document the tests

of the optical receivers, I set up a Twiki site and presented the results on two different IBL general meetings. The University of Bern joined the IBL effort while I was a student there. I partly built up the hardware activities . With my efforts, the lab became known throughout the IBL community. The University of Bern is still active in this field and considered as expert in terms of optical receivers, thanks to my contributions.

For my postdoctoral fellow position at TRIUMF, I joined the Inner Tracker (ITk) effort, a new tracker to be implemented during the phase 2 upgrade for the High Luminosity LHC around 2025. I started by using the validation software used for the present Inner Detector and applying it to ITk geometries and contributed to the studies to make a physics case for a large eta extension (up to $\eta = 4$) of the ITk. This software package is still in development and I represent the ITk responsible.

I further studied the effects of a new algorithm called TIDE (Tracking in dense environments), which was developed for run 2. In using this new algorithm for ITk geometries, I can help make decisions on the not yet fully defined detector layout. I supervise a PhD student in studying efficiencies as a function of the number of pixel and strip layers. All these studies are an important input to the ITk community in defining the best layout of the inner tracker.
